

Package ‘tidyoperators’

March 14, 2023

Title Infix operators for tidier R code

Version 0.0.9

Description The 'tidyoperators' R-package adds some much needed infix operators, and a few functions, to make your R code much more tidy. It includes infix operators for the negation of logical operators (exclusive-or, not-and, not-in), safer float (in)equality operators, in-place modifying mathematical arithmetic, string arithmetic, string sub-setting, in-place modifying string arithmetic, in-place modifying string sub-setting, and in-place modifying unreal replacers. The 'tidyoperators' R-package also adds the stringi-like `stri_locate_ith` function. It also adds string functions to replace, extract, add-on, transform, and re-arrange, the `ith` pattern occurrence or position. And it includes some helper functions for more complex string arithmetic. Most stringi pattern expressions options (regex, fixed, coll, charclass) are available for all string-pattern-related functions, when appropriate. This package adds the `transform_if` function. This package also allows integrating third-party parallel computing packages (like stringfish) for some of its functions.

float_logic	<i>Safer float (in)equality operators</i>
-------------	---

Description

The %f==%, %f!=% %f<%, %f>%, %f<=%, %f>=% operators perform "float logic". They are virtually equivalent to the regular (in)equality operators, ==, !=, <, >, <=, >=, except for one aspect. The float logic operators assume that if the absolute difference between x and y is smaller than the Machine tolerance, sqrt(.Machine\$double.eps), then x and y ought to be consider to be equal. Thus these provide safer float logic. For example: 0.1*7 == 0.7 returns FALSE, even though they are equal, due to the way floating numbers are stored in programming languages like R. But 0.1*7 %f==% 0.7 returns TRUE.

Usage

- x %f==% y
- x %f!=% y
- x %f<% y
- x %f>% y
- x %f<=% y
- x %f>=% y

Arguments

`x, y` numeric vectors, matrices, or arrays, though these operators were specifically designed for floats (class "double").

Examples

```
x <- c(0.3, 0.6, 0.7)
y <- c(0.1*3, 0.1*6, 0.1*7)
print(x); print(y)
x == y # gives FALSE, but should be TRUE
x != y # gives TRUE, should be FALSE
x > y # not wrong
x < y # gives TRUE, should be FALSE
x %f==% y # here it's done correctly
x %f!=% y # correct
x %f<% y # correct
x %f>% y # correct
x %f<=% y # correct
x %f>=% y # correct

# These operators still work for non-float numerics also:
x <- 1:5
y <- 1:5
x %f==% y
x %f!=% y
x %f<% y
x %f>% y
x %f<=% y
x %f>=% y

x <- 1:5
y <- x+1
x %f==% y
x %f!=% y
x %f<% y
x %f>% y
x %f<=% y
x %f>=% y

x <- 1:5
y <- x-1
x %f==% y
x %f!=% y
x %f<% y
x %f>% y
x %f<=% y
x %f>=% y
```

Description

In-place modifiers for addition, subtraction, multiplication, division, power, root, logarithm, and anti-logarithm.

`x %+ <-% y` is the same as `x <- x + y`

`x %- <-% y` is the same as `x <- x - y`

`x %* <-% y` is the same as `x <- x * y`

`x %/ <-% y` is the same as `x <- x / y`

`x %^ <-% p` is the same as `x <- x^p`

`x %rt <-% p` is the same as `x <- x^(1/p)`

`x %logb <-% b` is the same as `x <- log(x, base=b)`

`x %alogb <-% b` is the same as `x <- b^x`; if `b=exp(1)`, this is the same as `x <- exp(x)`

Usage

`x %+ <-% y`

`x %- <-% y`

`x %* <-% y`

`x %/ <-% y`

`x %^ <-% p`

`x %rt <-% p`

`x %logb <-% b`

`x %alogb <-% b`

Arguments

<code>x</code>	a number or numeric (or 'number-like') vector, matrix, or array.
<code>y</code>	a number, or numeric (or 'number-like') vector, matrix, or array of the same length/dimension as <code>x</code> . It gives the number to add, subtract, multiply by, or divide by.
<code>p</code>	a number, or a numeric vector of the same length as <code>x</code> . It gives the power to be used.
<code>b</code>	a number, or a numeric vector of the same length as <code>x</code> . It gives the logarithmic base to be used.

Value

These operators do not return any value: they are in-place modifiers, and thus modify `x` directly.

Examples

```
x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %+ <-% 3 # same as x <- x + 3
print(x)

x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %- <-% 3 # same as x <- x - 3
print(x)

x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %* <-% 3 # same as x <- x * 3
print(x)

x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %/ <-% 3 # same as x <- x / 3
print(x)

x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %^ <-% 3 # same as x <- x^3
print(x)

x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %rt <-% 3 # same as x <- x^(1/3)
print(x)

x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %logb <-% 3 # same as x <- log(x, base=3)
print(x)

x <- matrix(rpois(10, 10), ncol=2)
print(x)
x %alogb <-% 3 # same as x <- 3^x
print(x)

x <- 3
print(x)
x %alogb <-% exp(1) # same as x <- exp(x)
print(x)
exp(3) # notice this is the same.
```

Description

In-place modifier versions of string arithmetic:

`x %s+ <-% y` is the same as `x <- x %s+% y`

`x %s- <-% p` is the same as `x <- x %s-% p`

`x %s* <-% n` is the same as `x <- x %s*% n`

`x %s/ <-% p` is the same as `x <- x %s/% p`

See also the documentation on string arithmetic: [string arithmetic](#).

Note that there is no in-place modifier versions of `%ss%`, `s_extract()`, and `s_repl()`.

Usage

```
x %s+ <-% y
```

```
x %s- <-% p
```

```
x %s* <-% n
```

```
x %s/ <-% p
```

Arguments

`x`, `y`, `p`, `n` see [string arithmetic](#) and [s_pattern](#).

Value

These operators do not return any value: they are in-place modifiers, and thus modify `x` directly.

Examples

```
y <- "a"
p <- "a|e|i|o|u"
n <- c(2, 3)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s+ <-% y # same as x <- x %s+% y
print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s- <-% p # same as x <- x %s-% p
print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s* <-% n # same as x <- x %s\*% n
```

```

print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s/ <-% p # same as x <- x %s/% p
print(x)

#####

y <- "a"
# pattern with ignore.case=TRUE:
p <- s_pattern(regex = "A|E|I|O|U", ignore.case=TRUE)
n <- c(3, 2)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s+ <-% y # same as x <- x %s+% y
print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s- <-% p # same as x <- x %s-% p
print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s* <-% n # same as x <- x %s\\*% n
print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %s/ <-% p # same as x <- x %s/% p
print(x)

```

inplace_str_subset	<i>In place modifying string subsetting</i>
--------------------	---

Description

In-place modifier versions of string subsetting:

`x %sget <-% ss` is the same as `x <- x %sget% ss`

`x %strim <-% ss` is the same as `x <- x %strim% ss`

See also the documentation on string subsetting ([string subset](#)).

Note that there is no in-place modifier versions of `%ss%`.

Usage

```
x %sget <-% ss

x %strim <-% ss
```

Arguments

x, ss see [string subset](#).

Value

These operators do not return any value: they are in-place modifiers, and thus modify x directly.

Examples

```
ss <- c(2,2)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %sget <-% ss # same as x <- x %sget% ss
print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %strim <-% ss # same as x <- x %strim% ss
print(x)

#####

ss <- c(2,2)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %sget <-% ss # same as x <- x %sget% ss
print(x)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
x %strim <-% ss # same as x <- x %strim% ss
print(x)
```

inplace_unreal

In-place unreal replacers

Description

In-place modifiers to replace unreal (NA, NaN, Inf, -Inf) elements.

Works on vectors, matrices, and arrays.

The following

```
x %unreal <-% 0
```

is the same as
`x[is.na(x)|is.nan(x)|is.infinite(x)] <- 0`

Usage

```
x %unreal <-% replacement
```

Arguments

`x` a vector or matrix whose unreal values are to be replaced.
`replacement` the replacement value.

Value

This operator does not return any value: it is an in-place modifiers, and thus modifies `x` directly. The `x` vector is modified such that all NA, NaN and infinities are replaced with the given replacement value.

Examples

```
x <- c(1:9, NA, NaN, Inf)
print(x)
x %unreal <-% 0 # same as x[is.na(x)|is.nan(x)|is.infinite(x)] <- 0
print(x)
```

logic_ops

Logic operators

Description

Additional logic operators:

The `x %xor% y` operator is the "exclusive-or" operator, the same as `xor(x, y)`.

The `x %n%&% y` operator is the "not-and" operator, the same as `(!x) & (!y)`.

The `x %out% y` operator is the same as `!x %in% y`.

The `x %?=% y` operator checks if `x` and `y` are **both** unreal or unknown (i.e. NA, NaN, Inf, -Inf).

The `n %=numtype% numtype` operator is a vectorized operator that checks for every value of numeric vector `n` if it can be considered a number belonging to type `numtype`. See arguments for details.

The `s %=strtype% strtype` operator is a vectorized operator that checks for every value of character vector `s` if it can be seen as a certain `strtype`. See arguments for details.

The `s %sgrep% p` operator is a vectorized operator that checks for every value of character vector `s` if it has pattern `p`.

Usage

`x %xor% y`

`x %n&% y`

`x %out% y`

`x %?=% y`

`s %sgrep% p`

`n %=numtype% numtype`

`s %=strtype% strtype`

Arguments

<code>x, y</code>	see Logic .
<code>s</code>	a character vector.
<code>p</code>	the result from s_pattern , or else a character vector of the same length as <code>s</code> with regular expressions.
<code>n</code>	a numeric vector.
<code>numtype</code>	<p>a single string giving the type if numeric to be checked. The following options are supported:</p> <ul style="list-style-type: none"> • <code>"~0"</code>: zero, or else a number whose absolute value is smaller than the Machine tolerance (<code>sqrt(.Machine\$double.eps)</code>). • <code>"B"</code>: binary numbers (exactly 0 or exactly 1); • <code>"prop"</code>: proportions - numbers between 0 and 1 (exactly 0 or 1 is also allowed); • <code>"N"</code>: Natural numbers (non-negative integers including zero); • <code>"I"</code>: Integers; • <code>"odd"</code>: odd integers; • <code>"even"</code>: even integers; • <code>"R"</code>: Real numbers; • <code>"unreal"</code>: infinity, NA, or NaN;
<code>strtype</code>	<p>a single string giving the type of string to be checked. The following options are supported:</p>

- "empty": checks if the string only consists of empty spaces.
- "unreal": checks if the string is NA, or if it has literal string "NA", "NaN" or "Inf", regardless if it has leading or trailing spaces.
- "numeric": checks if the string can be converted to a number, disregarding leading and trailing spaces. I.e. the string "5.0" can be converted to the actual number 5.0.
- "special": checks if the string consists of only special characters.

Examples

```
x <- c(TRUE, FALSE, TRUE, FALSE, NA, FALSE, TRUE)
y <- c(FALSE, TRUE, TRUE, FALSE, NA, NA, NA)
cbind(x, y, "x %xor% y"=x %xor% y, "x %n&% y" = x %n&% y, "x %?=% y" = x %?=% y)

1:3 %out% 1:10
1:10 %out% 1:3

n <- c(0:5, 0:-5, 0.1, -0.1, 0, 1, Inf, -Inf, NA, NaN)
1e-20 %=numtype% "~0"
n[n %=numtype% "B"]
n[n %=numtype% "prop"]
n[n %=numtype% "N"]
n[n %=numtype% "I"]
n[n %=numtype% "odd"]
n[n %=numtype% "even"]
n[n %=numtype% "R"]
n[n %=numtype% "unreal"]

s <- c(" AbcZ123 ", " abc ", " 1.3 ", " !#$%^&*() ", " ", " NA ", " NaN ", " Inf ")
s[s %=strtype% "empty"]
s[s %=strtype% "unreal"]
s[s %=strtype% "numeric"]
s[s %=strtype% "special"]

s <- c("Hello world", "Goodbye world")
p <- s_pattern(regex = c("Hello", "Hello"))
s %sgrep% p
```

stri_locate_ith

Locate the i^{th} occurrence of a pattern

Description

The `stri_locate_ith` function locates the i^{th} occurrence of a pattern in each string of some character vector.

Usage

```
stri_locate_ith(x, i, ..., regex, fixed, coll, charclass, simplify = FALSE)
```

Arguments

- | | |
|-------------------------------|--|
| x | a string or character vector. |
| i | <p>a number, or a numeric vector of the same length as x. This gives the i^{th} instance to be replaced.</p> <p>Positive numbers are counting from the left. Negative numbers are counting from the right. I.e.:</p> <p><code>stri_locate_ith(x, i=1, p, rp)</code> gives the position (range) of the first occurrence of pattern p.</p> <p><code>stri_locate_ith(x, i=-1, p, rp)</code> gives the position (range) of the last occurrence of pattern p.</p> <p><code>stri_locate_ith(x, i=2, p, rp)</code> gives the position (range) of the second occurrence of pattern p.</p> <p><code>stri_locate_ith(x, i=-2, p, rp)</code> gives the position (range) of the second-last occurrence of pattern p.</p> <p>If <code>abs(i)</code> is larger than the number of instances, the first (if $i < 0$) or last (if $i > 0$) instance will be given.</p> <p>For example: suppose a string has 3 instances of p;
 then if $i = 4$ the third instance will be located,
 and if $i = -4$ the first instance will be located.</p> |
| ... | more arguments to be supplied to stri_locate . |
| regex, fixed, coll, charclass | character vector of search patterns, as in stri_locate . |
| simplify | <p>either TRUE or FALSE (default = FALSE):</p> <ul style="list-style-type: none"> • If FALSE, <code>stri_locate_ith</code> returns a list, usable in the stri_sub_all functions (for example: to transform all matches). • If TRUE, <code>stri_locate_ith</code> returns an integer matrix of positions and lengths. |

Value

If `simplify = FALSE`, this returns a list, one element for each string. Each list element consists of a matrix with 2 columns and one row:

The first column gives the start position of the i^{th} occurrence of pattern p.

The second column gives the end position of the i^{th} occurrence of pattern p.

When `simplify=FALSE`, the results can be used in the `from` argument in the [stri_sub_all](#) functions, for example to transform the i^{th} matches (see examples section below).

If `simplify = TRUE` (default), this returns an integer matrix with 3 columns:

The first column gives the start position of the i^{th} occurrence of pattern p.

The second column gives the end position of the i^{th} occurrence of pattern p.

The third column gives the length of the position range of the i^{th} occurrence of pattern p.

Examples

```
# simple pattern ====

x <- rep(paste0(1:10, collapse=""), 10)
print(x)
out <- stri_locate_ith(x, 1:10, regex = as.character(1:10), simplify=TRUE)
cbind(1:10, out)

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
p <- rep("a|e|i|o|u", 2)
out <- stri_locate_ith(x, c(-1, 1), regex=p, simplify=TRUE)
print(out)
substr(x, out[,1], out[,2])

#####

# ignore case pattern ====

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
p <- rep("A|E|I|O|U", 2)
out <- stri_locate_ith(x, c(1, -1), regex=p, case_insensitive=TRUE, simplify=TRUE)
substr(x, out[,1], out[,2])

#####

# multi-character pattern ====

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
# multi-character pattern:
p <- rep("AB", 2)
out <- stri_locate_ith(x, c(1, -1), regex=p, simplify=TRUE, case_insensitive=TRUE)
print(out)
substr(x, out[,1], out[,2])

#####

# Replacement transformation using stringi ====

x <- c("hello world", "goodbye world")
loc <- stri_locate_ith(x, c(1, -1), regex="a|e|i|o|u", simplify = FALSE)
extr <- stringi::stri_sub_all(x, from=loc)
repl <- lapply(extr, \(x)chartr(x, old = "a-zA-Z", new = "A-Za-z"))
stringi::stri_sub_all_replace(x, loc, replacement=repl)
```

str_arithmetic

*String arithmetic***Description**

String arithmetic operators.

The `x %s+% y` operator is equivalent to `paste0(x,y)`.

The `x %s-% p` operator removes character/pattern defined in `p` from `x`.

The `x %s*% n` operator repeats every element of `x` for `n` times, and glues them together.

The `x %s/% p` operator counts how often regular expression or character pattern `p` occurs in each element of `x`.

Usage

`x %s+% y`

`x %s-% p`

`x %s*% n`

`x %s/% p`

Arguments

<code>x</code>	a string or character vector.
<code>y</code>	a string, or a character vector of the same length as <code>x</code> .
<code>p</code>	the result from s_pattern , or else a character vector of the same length as <code>x</code> with regular expressions.
<code>n</code>	a number, or a numeric vector of the same length as <code>x</code> .

Details

These operators and functions serve as a way to provide straight-forward string arithmetic, missing from base R.

Value

The `%s+%`, `%s-%`, and `%s*%` operators return a character vector of the same length as `x`.

The `%s/%` returns a integer vector of the same length as `x`.

Examples

```
x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
y <- c("a", "b")
p <- rep("a|e|i|o|u", 2) # same as p <- s_pattern(regex=rep("a|e|i|o|u", 2))
n <- c(3, 2)

x %s+% y # =paste0(x,y)
x %s-% p # remove all vowels from x
x %s*% n
x %s/% p # count how often vowels appear in each string of vector x.
```

```
#####
```

```
x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
y <- "a"
# pattern that ignores case:
p <- s_pattern(regex=rep("A|E|I|O|U", 2), ignore.case=TRUE)
n <- c(2, 3)

x %s+% y # =paste0(x,y)
x %s-% p # remove all vowels from x
x %s*% n
x %s/% p # count how often vowels appears in each string of vector x.
```

str_subset_ops

String subsetting operators

Description

String subsetting operators.

The `x %ss% s` operator allows indexing a single string as-if it is an iterable object.

The `x %sget% ss` operator gives a certain number of the first and last characters of `x`.

The `x %strim% ss` operator removes a certain number of the first and last characters of `x`.

Usage

```
x %ss% s
```

```
x %sget% ss
```

```
x %strim% ss
```

Arguments

<code>x</code>	a string or character vector.
<code>s</code>	a numeric vector giving the subset indices.
<code>ss</code>	a vector of length 2, or a matrix with 2 columns with <code>nrow(ss)==length(x)</code> . The object <code>ss</code> should consist entirely of non-negative integers (thus 0, 1, 2, etc. are valid, but -1, -2, -3 etc are not valid). The first element/column of <code>ss</code> gives the number of characters counting from the left side to be extracted/removed from <code>x</code> . The second element/column of <code>ss</code> gives the number of characters counting from the right side to be extracted/removed from <code>x</code> .

Details

These operators serve as a way to provide straight-forward string sub-setting.

Value

The `%ss%` operator always returns a vector or matrix, where each element is a single character.

Examples

```
x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
ss <- c(2,3)
x %sget% ss

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
ss <- c(1,0)
x %sget% ss

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
ss <- c(2,3)
x %strim% ss

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
ss <- c(1,0)
x %strim% ss
```

substr_repl

*Sub-string functions***Description**

Fully vectorized sub-string functions.

These functions extract, replace, add-in, transform, or re-arrange, the i^{th} pattern occurrence or position range.

The substr_repl(x, rp, ...) function replaces a position (range) with string rp.

The substr_chartr(x, old, new, ...) function transforms the sub-string at a position (range) using chartr(old, new).

The substr_addin(x, addition, side, ...) function adds the additional string addition at the side (specified by argument side) of a position.

The substr_extract(x, type, ...) function extracts the string at, before, or after some position.

The substr_arrange(x, arr, ...) function sorts or reverse the sub-string at a position (range).

Usage

```
substr_repl(x, rp, ..., loc = NULL, start = NULL, end = NULL, fish = FALSE)
```

```
substr_chartr(
  x,
  old = "a-zA-Z",
  new = "A-Za-z",
  ...,
  loc = NULL,
  start = NULL,
  end = NULL,
  fish = FALSE
)
```

```
substr_addin(
  x,
  addition,
  side = "after",
  ...,
  loc = NULL,
  at = NULL,
  fish = FALSE
)
```

```
substr_extract(
  x,
```

```

    type = "at",
    ...,
    loc = NULL,
    start = NULL,
    end = NULL,
    fish = FALSE
  )

  substr_arrange(
    x,
    arr = "incr",
    ...,
    loc = NULL,
    start = NULL,
    end = NULL,
    fish = FALSE
  )

```

Arguments

x	a string or character vector.
rp	a string, or a character vector of the same length as x, giving the replacing strings.
...	only applicable if fish=TRUE; other arguments to be passed to the stringfish functions.
loc	The result from the stri_locate_ith function. It does not matter if the result is in the list form (simplify = FALSE), or in the matrix form (simplify = TRUE). See stri_locate_ith . NOTE: you cannot fill in both loc and start,end, or both loc and at. Choose one or the other.
start, end	integers, or integer vectors of the same length as x, giving the start and end position of the range to be modified.
fish	although tidyoperators has no dependencies other than stringi, it does allow the internal functions to use the multi-threadable stringfish functions. To do so, set fish=TRUE; this requires stringfish to be installed.
old, new	see chartr . Defaults to old="a-zA-Z", new="A-Za-z", which means upper case characters will be transformed to lower case characters, and vice-versa.
addition	a string, or a character vector of the same length as x, giving the string(s) to add-in.
side	which side of the position to add in the string. Either "before" or "after".
at	an integer, or integer vector of the same length as x.
type	a single string, giving the part of the string to extract. 3 options available:

- type = "at": extracts the string part at the position range;
- type = "before": extracts the string part before the position range;
- type = "after": extracts the string part after the position range.

arr a single string, giving how the sub-string should be arranged. 3 options available:

- arr = "incr": sort the sub-string alphabetically.
- arr = "decr": sort the sub-string reverse alphabetically.
- arr = "rev": reverse the sub-string.

Details

These functions serve as a way to provide straight-forward sub-string modification and/or extraction.

All substr_ functions internally only use fully vectorized R functions (no loops or apply-like functions).

Value

A modified character vector. If no match is found in a certain string of character vector x, the unmodified string is returned. The exception is for the substr_extract() function: in this function, non-matches return NA.

Examples

```
# numerical substr ====

x <- rep("12345678910", 2)
start=c(1, 2); end=c(3,4)
substr_extract(x, start=start, end=end)
substr_extract(x, type="before", start=start, end=end)
substr_extract(x, type="after", start=start, end=end)
substr_repl(x, "??", start=start, end=end)
substr_chartr(x, start=start, end=end)
substr_addin(x, " ", "after", at=end)
substr_addin(x, " ", "before", at=start)

start=10; end=11
substr_extract(x, start=start, end=end)
substr_extract(x, type="before", start=start, end=end)
substr_extract(x, type="after", start=start, end=end)
substr_repl(x, "??", start=start, end=end)
substr_chartr(x, start=start, end=end)
substr_addin(x, " ", "after", at=end)
substr_addin(x, " ", "before", at=start)

start=5; end=6
substr_extract(x, start=start, end=end)
substr_extract(x, type="before", start=start, end=end)
substr_extract(x, type="after", start=start, end=end)
substr_repl(x, "??", start=start, end=end)
substr_chartr(x, start=start, end=end)
substr_addin(x, " ", "after", at=end)
substr_addin(x, " ", "before", at=start)

#####
```

```
# simple pattern ====

x <- c("goodGOODGoodgOod", "goodGOODGoodgOod", paste0(letters[1:13], collapse=""))
print(x)
loc <- stri_locate_ith(
  # locate second-last occurrence of "good" of each string in x:
  x, -2, regex="good", case_insensitive=TRUE
)
substr_extract(x, loc=loc) # extract second-last "good"
substr_repl(x, c("??", "!!", " "), loc=loc) # replace second-last "good"
substr_chartr(x, loc=loc) # switch upper/lower case of second-last "good"
substr_addin(x, c(" ", "~", " "), "after", loc=loc) # add white space after second-last "good"
substr_addin(x, c(" ", "~", " "), "before", loc=loc) # add white space before second-last "good"
substr_arrange(x, loc=loc) # sort second-last "good"
substr_arrange(x, "rev", loc=loc) # reverse second-last "good"
substr_arrange(x, "decr", loc=loc) # reverse-sort second-last "good"
```

s_pattern

Pattern attribute assignment

Description

The %s-% and %s/% operators, their in-place equivalents, as well as the %sgrep% operator, all perform pattern matching for some purpose. By default the pattern matching is interpreted as case-sensitive regex patterns from `stringi`.

The `s_pattern` function allows the user to specify exactly how the pattern should be interpreted. To use more refined pattern definition, simply replace the right-hand-side expression `p` in the relevant operators with a call from the `s_pattern()` function.

The `s_pattern()` function uses the exact same argument convention as `stringi`. For example:

- `s_pattern(regex=p, case_insensitive=FALSE, ...)`
- `s_pattern(fixed=p, ...)`
- `s_pattern(coll=p, ...)`
- `s_pattern(boundary=p, ...)`
- `s_pattern(charclass=p, ...)`

All arguments in `s_pattern()` are simply passed to the appropriate functions in `stringi`.

For example:

`x %s/% p` counts how often regular expression `p` occurs in `x`,

whereas `x %s/% s_pattern(fixed=p, case_insensitive=TRUE)` will do the same, except it uses fixed (i.e. literal) expression, and it does not distinguish between upper case and lower case characters.

For consistency with base R and with packages such as `stringr`, one can also fill in `ignore.case=TRUE` or `ignore_case=TRUE` instead of `case_insensitive=TRUE`, and `s_pattern` will still understand that.

Usage

```
s_pattern(...)
```

Arguments

... pass stringi arguments here. I.e. regex=p, boundary=p, coll=p, charclass=p, case_insensitive=FALSE, etc. See the documentation in the stringi R package.

Details

The s_pattern() function only works in combination with the functions and operators in this package. It does not affect functions from base R or functions from other packages.

Value

The s_pattern(...) call returns a list with arguments that will be passed to the appropriate functions in stringi.

Examples

```
x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
p <- rep("a|e|i|o|u", 2) # same as p <- s_pattern(regex=rep("a|e|i|o|u", 2))
x %s/% p # count how often vowels appear in each string of vector x.

x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)
p <- s_pattern(regex=rep("A|E|I|O|U", 2), ignore.case=TRUE)
x %s/% p # count how often vowels appear in each string of vector x.
```

s_strapply

s_strapply

Description

The s_strapply(x, fun, w=F, clp=NULL, custom_apply=NULL) function applies the following steps to every element (every string) of character vector x:

1. the string is split into a vector of single characters (w=F), or a vector of space-delimited words (w=T).
2. the function fun() is applied to the vector from step 1.
3. the result from step 2 is pasted together to form a single string element again, using paste0(..., collapse=clp).

The point of this function is to increase the flexibility and usefulness of the other string operators in this package.

Usage

```
s_strapply(x, fun, w = FALSE, clp = NULL, custom_apply = NULL)
```

Arguments

x	a string or character vector.
fun	a function with a single input argument to be applied to the splitted string. Due what this function actually does (see description), additional arguments need to be specified within the function definition.
w	logical; should each string in character vector x be splitted into space-delimited words (w=T), or into single characters (w=F).
clp	how should each string be pasted together? If NULL (Default), the string is pasted together using <code>paste0(..., collapse="")</code> if w=F, and using <code>paste0(..., collapse=" ")</code> if w=T.
custom_apply	a function. <code>s_strapply()</code> internally uses <code>apply</code> . The user may choose to replace this with a custom apply-like function, usually for multi-threading purposes. <code>custom_apply</code> must have the same argument convention as <code>apply</code> , or else use the arguments x and fun. For example: <code>plan(multisession)</code> <code>s_strapply(..., custom_apply=future.apply::future_apply)</code> NOTE: It's better not to use multi-threading inside fun itself.

Value

The `s_strapply()` function generally returns a character vector of the same length as x, although this could depend on the function chosen for fun.

Examples

```
x <- c(paste0(letters[1:13], collapse=""), paste0(letters[14:26], collapse=""))
print(x)

# get which letter of the alphabet every character is:
s_strapply(x, fun=\(x)match(tolower(x), letters), clp=",")

# shuffle words randomly:
s_strapply(x, w=TRUE, fun=\(x)sample(x))

# completely customized sorting of characters (first vowels, then the rest of the letters):
custom_order <- c("a", "e", "i", "o", "u", setdiff(letters, c("a", "e", "i", "o", "u")))
print(paste0(custom_order, collapse = ""))
s_strapply(x, fun=\(x){
  rest <- setdiff(x = unique(x), y = custom_order)
  y <- factor(x = x, levels = c(custom_order, rest), ordered = TRUE)
  return(sort(y))
})
```

Description

Welcome to the tidyoperators help page!

The 'tidyoperators' R-package adds some much needed infix operators, and a few functions, to make your R code much more tidy. It includes infix operators for the negation of logical operators (exclusive-or, not-and, not-in), safer float (in)equality operators, in-place modifying mathematical arithmetic, string arithmetic, string sub-setting, in-place modifying string arithmetic, in-place modifying string sub-setting, and in-place modifying unreal replacers. The 'tidyoperators' R-package also adds the stringi-like `stri_locate_ith` function. It also adds string functions to replace, extract, add-on, transform, and re-arrange, the `ith` pattern occurrence or position. And it includes some helper functions for more complex string arithmetic. Most stringi pattern expressions options (regex, fixed, coll, charclass) are available for all string-pattern-related functions, when appropriate. This package adds the `transform_if` function. This package also allows integrating third-party parallel computing packages (like stringfish) for some of its functions.

The tidyoperators R package adds the following functionality:

- [Infix logical operators](#) for exclusive-or, not-and, not-in, number-type, and string-type.
- [Safer \(in\)equality operators for floating numbers](#).
- Infix operators for [In-place modifiers for mathematical arithmetic](#).
- Infix operators for [string arithmetic](#).
- Infix operators for [string sub-setting](#).
- Infix operators for [In-place modifying string arithmetic](#).
- Infix operators for [In-place modifying string sub-setting](#).
- [The in-place modifying unreal replacer operator](#).
- [stri_locate_ith](#): The stringi R package has a "locate_all" function, but no "locate_ith" function. The tidyoperators package adds the [stri_locate_ith](#) function, which uses the same naming and argument convention as the rest of the stringi functions, thus keeping your code consistent.
- The fully vectorized [sub-string functions](#), that extract, replace, add-in, transform, or re-arrange, the `ith` pattern occurrence or location.

- There are also some string helper functions, namely `s_pattern` and `s_strapply`.
- The `transform_if` function, and some related operators.
- Most `stringi` pattern expressions options (regex, fixed, coll, charclass) are available for all string-pattern-related functions, when appropriate.
- This R package has only one dependency: `stringi`. No other dependencies, as to avoid "dependency hell".
- Although this package has no other dependencies, it allows multi-threading of functions (when appropriate) through third-party packages (like `stringfish`).

Please also have a look at the Read-Me file on the Github mian page of this package: <https://github.com/tony-aw/tidyoperators>

Usage

```
tidyoperators_help()
```

transform_if

The transform_if function and the subset_if operators

Description

Consider the following code:

```
x[cond(x)] <- f(x[cond(x)])
```

Here a conditional subset of the object `x` is transformed with function `f`, where the condition is using a function referring to `x` itself (namely `cond(x)`). Consequently, reference to `x` is written four times!

The `tidyoperators` package therefore adds the `transform_if()` function which will tidy this up.

```
x <- transform(x, cond, trans)
```

is exactly equivalent to

```
x[cond(x)] <- trans(x[cond(x)])
```

Besides `transform_if`, the `tidyoperators` package also adds 2 "subset_if" operators:

The `x %[if]% cond` operator selects elements from vector/matrix/array `x`, for which the result of `cond(x)` returns TRUE.

The `x %[!if]% cond` operator selects elements from vector/matrix/array `x`, for which the result of `cond(x)` returns FALSE.

Usage

```
transform_if(x, cond, trans = NULL)
```

```
x %[if]% cond
```

```
x %[!if]% cond
```

Arguments

x a vector, matrix, or array.

cond a function that returns a binary logic (TRUE, FALSE) vector of the same length/dimensions as x (for example: `is.na`).

- Elements of x for which `cond(x)==TRUE` are transformed / selected;
- Elements of x for which `cond(x)==FALSE` are not transformed /selected.

trans the transformation function to use. For example: `log`.

Details

The `transform_if(x, cond, trans)` function does not rely on any explicit or implicit loops, nor any third-party functions.

Value

The `transform_if()` function returns the same object x, with the same dimensions, except with the subset transformed.

Note that this function **returns** object x, to modify x directly, one still has to assign it. To keep your code tidy, consider combining this function with `magrittr`'s in-place modifying piper-operator (`%<>%`). I.e.:

```
very_long_name_1 %<>% transform_if(cond, trans)
```

The `subset_if` - operators all return a vector with the selected elements.

Examples

```
object_with_very_long_name <- matrix(-10:9, ncol=2)
print(object_with_very_long_name)
object_with_very_long_name |> transform_if(\(x)x>0, log)
object_with_very_long_name %[if]% \(x)x %in% 1:10
object_with_very_long_name %[!if]% \(x)x %in% 1:10
```

%m import <-%	<i>Utility operator</i>
---------------	-------------------------

Description

The alias %m import <-% pkgs operator imports multiple R package under the same alias.

The alias %m import <-% pkgs command is essentially the same as `alias <- loadNamespace("packagename")` except the alias %m import <-% pkgs operator allows assigning multiple packages to the same alias, and this operator does not import internal functions (i.e. internal functions are kept internal, as they should).

For example:

```
fv %m import <-% c("data.table", "collapse", "tidytable")
```

The alias %m import <-% pkgs operator will tell the user about conflicting objects. It will also inform the user when importing a package that consists mostly of infix operators.

Usage

```
alias %m import <-% pkgs
```

Arguments

alias	a variable name (unquoted), giving the (not yet existing) object where the package(s) are to be assigned to.
pkgs	a character vector with the package name(s). NOTE: The order matters! If 2 packages share objects with the same name, the package named last will overwrite the earlier named package.

Value

The variable named in the alias argument will be created (if it did not already exist), and it will contain the (merged) package environment.

Examples

```
## Not run:
fv %m import <-% c("data.table", "collapse", "tidytable")

## End(Not run)
```
